## Abstract of EP0674300

A means (21) of defining the position of the aircraft is compared with a database (22) relating to the local environment and the runway by a primary comparator (23). The touchdown coordinates on the runway are extracted by a calculating system (24) and the approach slope vector is calculated. The real approach slope vector and theoretical approach slope vector are compared in a secondary comparator. The horizontal difference between real and theoretical approach vectors is compared with a safe threshold.
